Abstract

The Stokes problem and the linear elasticity problems can be viewed as a mixed variational formulation. These formulations are discretized by means of the $hp$-version of the finite element method. The system of linear algebraic equations is solved by the preconditioned Bramble-Pasciak conjugate gradient method. The development of an efficient preconditioner requires three ingredients, a preconditioner related to the components of the velocity modes, a preconditioner for the Schur complement related to the components of the pressure modes and a discretization by a stable finite element pair which satisfies the discrete inf-sup-condition. The last condition is also important in order to obtain a stable discretization scheme. The preconditioner for the velocity modes is adapted from fast $hp$-FEM preconditioners for elliptic problems. Moreover, we will prove that the preconditioner for the Schur complement can be chosen as a diagonal matrix if the pressure is discretized by discontinuous finite elements. We will prove that the system of linear algebraic equations can be solved in almost optimal complexity if the $Q_k - P_{k-1,\text{disc}}$ element is used. This yields to quasioptimal $hp$-FEM solvers for the Stokes problems and linear elasticity problems. The latter are robust with respect to the contraction ratio $\nu$. The efficiency of the presented solver is shown in several numerical examples.

1 Introduction

The numerical solution of boundary value problems (BVP) of partial differential equations (PDE) is one of the major challenges in Computational Mathematics. Finite element methods (FEM) are among the most powerful tools in order to compute an approximate solution of BVP. For the $h$-version of the FEM, the polynomial degree $k$ of the shape functions on the elements is kept constant and the mesh-size $h$ is decreased. This is in contrast to the $p$-version of the FEM in which the polynomial degree $k$ is increased and the mesh-size $h$ is kept constant. Both ideas, mesh refinement and increasing the polynomial degree, can be combined. This is called the $hp$-version of the FEM. The advantage of the $p$-version in comparison to the $h$-version is that the solution converges much faster to the exact solution with respect to the dimension $N$ of the approximation space, see e.g. [45], [46], [19] and the references therein as well as [29] for the related spectral element methods.

For elliptic problems, preconditioned conjugate gradient (PCG) methods with additive Schwarz preconditioners (ASM) as domain decomposition (DD) are a powerful tool for the development of fast and efficient solvers for the $h$-version as well as for the $p$-version of the FEM, see [1,5,7,8,10,17,20,26,28,31,36,37]. The extension to linear elasticity problems is straightforward, [9]. Based on Korn’s inequality, [21], an optimal but nonrobust preconditioner is obtained by using a preconditioner for the potential equation for each component of the displacement $u$.

In this paper, we will investigate the efficient solution of linear systems of algebraic equations of \( hp \)-FEM finite element discretizations of mixed formulations. One application will be the development of robust solvers for linear elasticity. For nearly incompressible materials, the constants in Korn’s inequality are very close to 0. In order to overcome this problem, a Lagrange multiplier \( p = -\lambda \nabla \cdot \mathbf{u} \) is introduced leading to a mixed problem. Mixed finite elements, see [16], are also used for saddle point problems such as the Stokes problem which is another application. An overview on flow problems is given in the monographs [31], [25]. The most important analytical tool for the development of a stable approximation scheme is the so-called inf-sup condition between the velocity \( \mathbf{u} \), or the displacement \( \mathbf{u} \), and the pressure \( p \), which has to be verified for the corresponding pair of approximation spaces, see [14], [21]. In the \( h \)-version, stable element pairs are the Rannacher-Turek element, [42], the mini element, [48], the \( Q_2 - Q_1 \)-element and the elements with jumping pressure, [18]. In the \( p \)-version, the \( Q_k - Q_{k-2} \) element is stable with respect to \( h \), [47], see also [43], [44]. However, there is some dependence with respect to the polynomial degree \( k \). The analysis for the related spectral element method has been done in [40], [39]. Another element is the \( Q_k - P_{k-1,\text{disc}} \) element. Bernardi and Maday showed that the inf-sup-constant of a single element of this type is independent both of \( h \) and \( k \), [6]. With the macroelement technique of [44], one can then conclude that a whole mesh of elements of this type is inf-sup-stable independently of \( h \) and \( k \). Using continuous pressure, Ainsworth and Coggins found an element which is inf-sup-stable uniformly with respect to both \( h \) and \( k \) for 2D [2] by using a truncated pressure space.

The discretization of the Stokes problem or the Lamé-equations in the mixed formulation leads to an indefinite system of linear algebraic equations, which can be solved by an preconditioned UZAWA algorithm or GMRES. An alternative is the Bramble-Pasciak CG, [11], [49]. In this solution method, an inner product is defined in which the energetic inner product is positive definite. DD-methods for the Stokes problem have been considered in [13] for the \( h \)-version, in [4] for the \( p \)-version, and in [38], [24] for the related spectral element method.

The aim of this paper is the development of fast solvers for \( hp \)-FEM discretizations of mixed problem in \( \mathcal{O}(N \log^{3/2} N) \) floating point operations, where \( N \) is the number of unknowns. The solvers use the preconditioned Bramble-Pasciak CG. The main ingredients of the solution method are an \( H^1 \) elliptic solver for the velocity part of the system, a inf-sup-stable finite element pair and a solver related to the mass matrix corresponding to the pressure modes. The solver for the velocity modes is an extension of the DD-based preconditioners in [8], [9] for elliptic problems. The stable \( Q_k - P_{k-1,\text{disc}} \) element, [6], is the preferred finite element pair. Since the preconditioner for the pressure modes can be chosen as mass matrix, the derivation of a fast solver for the mass matrix is an important ingredient for the development of an efficient solution method.

The outline of the paper is as follows. The setting of the problem is described in Section 2. The discretization with \( hp \)-finite elements is described in section 3. Section 4 deals with the numerical solution of the system of linear algebraic equations. Several numerical experiments are presented in Section 5.

Throughout this paper, the integer \( k \) denotes the polynomial degree. For two real symmetric and positive definite \( n \times n \) matrices \( A, B \), the relation \( A \preceq B \) means that \( A - cB \) is negative definite, where \( c > 0 \) is a constant independent of \( h \), or \( k \). The relation \( A \sim B \) means \( A \preceq B \) and \( B \preceq A \), i.e. the matrices \( A \) and \( B \) are spectrally equivalent. The isomorphism between a function \( u = \sum_i u_i \psi_i \in L^2 \) and the vector of coefficients \( \mathbf{u} = [u_i] \) with respect to the basis \( [\Psi] = [\psi_1, \psi_2, \ldots] \) is denoted as \( u = [\Psi]_{\mathbf{u}} \).

2 Setting of the problem

In this paper, we consider the following problem. Let \( \Omega \subset \mathbb{R}^d \), \( d = 2, 3 \) be a bounded polygonal Lipschitz domain with \( \Gamma_0 \cap \Gamma_1 = \emptyset \), \( \Gamma_0 \cup \Gamma_1 = \partial \Omega \), \( \text{meas}(\Gamma_0) > 0 \). Moreover, let

\[
\mathbb{V} = H^1_0(\Omega, \mathbb{R}^d) = \{ u \in H^1(\Omega, \mathbb{R}^d), u |_{\Gamma_0} = 0 \} \quad \text{and} \quad \mathbb{Q} = \begin{cases} L^2_0(\Omega, \mathbb{R}^d) & \Gamma_1 = \emptyset \\ L^2(\Omega, \mathbb{R}^d) & \text{else} \end{cases}
\]
where $L^2_0(\Omega, \mathbb{R}^d) = \{ u \in L^2(\Omega, \mathbb{R}^d), \int_{\Omega} u \, dx = 0 \}$

Moreover, let
- $a(\cdot, \cdot)$ be a symmetric and bounded elliptic bilinear form on $\mathbb{V}$,
- $b(v, q) = -\int_{\Omega} q \, \text{div} \, v \, dx$, and
- $c(\cdot, \cdot)$ be a symmetric and bounded positive semidefinite bilinear form on $\mathbb{Q}$.

Finally, let

\[ F(v) := \int_{\Omega} f \cdot v \, dx + \int_{\Gamma_1} g \cdot v \, ds \]

with given $f \in L^2(\Omega, \mathbb{R}^d)$, $g \in L^2(\Gamma_1, \mathbb{R}^d)$. We are looking for solutions $(u, p) \in \mathbb{V} \times \mathbb{Q}$ such that

\[ a(u, v) + b(v, p) = F(v) \quad \text{for all} \quad v \in \mathbb{V}, \quad (1) \]

\[ b(u, q) - c(p, q) = 0 \quad \text{for all} \quad q \in \mathbb{Q}. \quad (2) \]

We present now two examples which are covered by this formulation and which will be considered in the following.

1. In the Stokes problem, we have

\[ a(u, v) = \nu \int_{\Omega} \text{grad} \, u : \text{grad} \, v \, dx, \]

\[ c(p, q) = 0 \]

with the parameter $\nu > 0$. Due to the existence of Dirichlet boundary conditions, the bilinear form $a(\cdot, \cdot)$ is $\mathbb{V}$ elliptic. Together with the inf-sup condition

\[ \inf_{0 \neq q \in \mathbb{Q}} \sup_{0 \neq v \in \mathbb{V}} \frac{b(v, q)}{\|v\|_{\mathbb{V}} \|q\|_{\mathbb{Q}}} \geq \beta_1 > 0, \quad (3) \]

existence and uniqueness of the Stokes problem can be proved, see e.g. [25].

2. The mixed formulation for linear elasticity is obtained from the system of the Lamé equations

\[ -\frac{E}{(1 + \nu)} \text{div} \, \varepsilon(u) = \frac{E \nu}{(1 + \nu)(1 - 2\nu)} \text{grad} \, \text{div} \, u = f \quad \text{in} \quad \Omega, \]

\[ u = 0 \quad \text{on} \quad \Gamma_0, \]

\[ \sigma(u) \cdot n = g \quad \text{on} \quad \Gamma_1, \]

where $E$ and $\nu$ are Young’s modulus and Poisson’s ratio. Here, $\varepsilon$ and $\sigma$ are the strain tensor and stress tensor given by the relations

\[ \varepsilon_{ij}(u) = \frac{1}{2} \left( \frac{\partial u_j}{\partial x_i} + \frac{\partial u_i}{\partial x_j} \right) \quad \text{and} \quad \sigma = \frac{E \nu}{(1 + \nu)(1 - 2\nu)} \text{trace}(\varepsilon) I + \frac{E}{(1 + \nu)} \varepsilon, \]

respectively.

The mixed formulation is obtained by introducing the hydrostatic pressure $p = -\lambda \text{div} \, u$ as additional variable. Then, one obtains [1], [2] with the specifications:

\[ a(u, v) = \frac{E}{(1 + \nu)} \int_{\Omega} \varepsilon(u) : \varepsilon(v) \, dx, \quad (4) \]

\[ c(p, q) = \frac{(1 + \nu)(1 - 2\nu)}{E \nu} \int_{\Omega} pq \, dx. \]
Using Korn’s second inequality the following seminorm equivalence, see \cite{35, 22}, it follows that
\[ c_K^2 |v|^2_{H^1} \leq \int_{\Omega} \varepsilon(v) : \varepsilon(v) \, dx \leq |v|^2_{H^1} , \]
where \( c_K \) is a constant depending on the geometry of \( \Omega \) and on the Dirichlet boundary \( \Gamma_0 \) only. The inf-sup condition \( \ref{eq:inf-sup-condition} \) guarantees existence and uniqueness of a weak solution \((u, p) \in \mathbb{V} \times \mathbb{Q} \). \cite{16}.

3 Galerkin discretization

The problem \((\ref{eq:weak-Problem}, \ref{eq:boundary-condition})\) is solved approximately by using Galerkin’s method. Therefore by choosing appropriate finite-dimensional subspaces \( \mathbb{V}_N \subset \mathbb{V} \), \( \mathbb{Q}_N \subset \mathbb{Q} \) with \( \dim(\mathbb{V}_N) + \dim(\mathbb{Q}_N) = N \) one can get an approximate solution of the above mentioned mixed variational problem \((\ref{eq:weak-Problem}, \ref{eq:boundary-condition})\). The approximate solution solves the discrete variational problem
\[
\begin{align*}
& a(u_N, v_N) + b(v_N, p_N) = F(v_N) \quad \text{for all } v_N \in \mathbb{V}_N, \quad (5) \\
& b(u_N, q_N) - c(p_N, q_N) = 0 \quad \text{for all } q_N \in \mathbb{Q}_N.
\end{align*}
\]
In order to ensure existence and uniqueness of a weak solution \((p_N, q_N) \in \mathbb{V}_N \times \mathbb{Q}_N\) in \((\ref{eq:finvar}), (\ref{eq:supvar})\), the discrete inf-sup condition
\[
\inf_{0 \neq q_N \in \mathbb{Q}_N} \sup_{0 \neq v_N \in \mathbb{V}_N} \frac{b(v_N, q_N)}{||v_N||_V ||q_N||_Q} \geq \beta_1 > 0 \quad (7)
\]
has to be satisfied. Then, the discrete mixed variational problem has a unique solution \((u_N, p_N) \in \mathbb{V}_N \times \mathbb{Q}_N\). \cite{16}. However, the error estimates depend strongly on \( \beta_1 \), e.g.
\[
\begin{align*}
& ||u - u_N||_V \geq \frac{1}{\beta_1} \inf_{v_N \in \mathbb{V}_N} ||u - v_N||_V + \frac{1}{\beta_1} \inf_{q_N \in \mathbb{Q}_N} ||p - q_N||_Q \\
& ||p - p_N||_Q \geq \frac{1}{\beta_1} \inf_{v_N \in \mathbb{V}_N} ||u - v_N||_V + \frac{1}{\beta_1} \inf_{q_N \in \mathbb{Q}_N} ||p - q_N||_Q,
\end{align*}
\]
see again \cite{16} concerning the details. Therefore, an independence of \( \beta_1 > 0 \) of the discretization parameters is important in order to get a stable approximation scheme. Note that in general the existence of a discrete inf-sup-constant \( \ref{eq:inf-sup-condition} \) does not follow from the continuous one \( \ref{eq:inf-sup-continuous} \). Therefore this condition has to be shown explicitly for each choice of space pairings \( \mathbb{V}_N \) and \( \mathbb{Q}_N \).

Now, we are able to describe the setup for the discrete problem. \( \Omega \) is a polygonal Lipschitz domain, which is decomposed into a triangulation \( \mathcal{T} \), consisting of isotropic quadrilateral (2D) or hexahedral (3D) elements \( \mathcal{R} \). With \( \mathcal{R} \) we denote the reference element \((-1, 1)^d\) with \( d = 2, 3 \). \( \Phi \) is a bilinear mapping from the reference element \( \mathcal{R} \) to the element \( \mathcal{R}_k \). \( \mathbb{Q}_k \) denotes the space of polynomials on \((-1, 1)^d\) with maximal degree \( k \) in each variable whereas \( \mathbb{P}_k \) denotes the space of polynomials on \((-1, 1)^d\) with maximal total degree \( k \). For the variable \( u \in \mathbb{V} \) we can now build the following \( hp \)-FEM space
\[
\mathbb{V}_k = \left\{ u \in \mathbb{V}, \quad u|_{\mathcal{R}_k} = \tilde{u} \circ \Phi_k^{-1}, \tilde{u} \in (\mathbb{Q}_k)^d \right\}. \quad (8)
\]
Several choices for \( \mathbb{Q}_N \) are considered as approximation space for the variable \( p \in \mathbb{P} \). In this paper, the \( \mathbb{Q}_k - \mathbb{P}_{k-1, \text{disc}}, \mathbb{Q}_k - \mathbb{P}_{k-2, \text{disc}}, \) the Taylor-Hood element and the \( \mathbb{Q}_k - \mathbb{Q}_{k-1,\text{cont}} \) element (only for \( d = 2 \)) are investigated. The corresponding pressure spaces are defined by the relations
\[
\begin{align*}
\mathbb{P}_{k-1} &= \{ p \in \mathbb{P}, \quad p|_{\mathcal{R}_k} = \tilde{p} \circ \Phi_k^{-1}, \tilde{p} \in \mathbb{P}_{k-1} \}, \\
\mathbb{Q}_{k-2} &= \{ p \in \mathbb{Q}, \quad p|_{\mathcal{R}_k} = \tilde{p} \circ \Phi_k^{-1}, \tilde{p} \in \mathbb{Q}_{k-2} \}, \\
\mathbb{Q}_{k-1,\text{cont}} &= \{ p \in \mathbb{Q}, \quad p|_{\mathcal{R}_k} = \tilde{p} \circ \Phi_k^{-1}, \tilde{p} \in \mathbb{Q}_{k-1} \}, \\
\mathbb{Q}_{k-1,\text{cont}}' &= \{ p \in \mathbb{Q}, \quad p|_{\mathcal{R}_k} = \tilde{p} \circ \Phi_k^{-1}, \tilde{p} \in \mathbb{Q}_{k-1} \}.
\end{align*}
\]
In a next step, the spaces are equipped with basis functions. The Legendre polynomials on $\mathbb{P}_k$ span \{x, y^i : i \in \{0, 1\}, 0 \leq j \leq k \ or \ 0 \leq i \leq k, j \in \{0, 1\}\}, respectively, see \cite{47, 3, 2}. The following lemma summarizes the behavior of the inf-sup constants.

Lemma 3.1. Let $\mathbb{V}_k, \mathbb{P}_{k-1}, \mathbb{Q}_{k-2}, \mathbb{Q}_{k-1, \text{cont}}$ and $\mathbb{Q}'_{k-1, \text{cont}}$ be defined by \cite{6} and \cite{9}, respectively. Then,

$$0 < \tilde{\beta}_1 \leq \inf_{0 \neq q_N \in \mathbb{P}_{k-1}} \sup_{0 \neq v_N \in \mathbb{V}_k} \frac{b(v_N, q_N)}{\|v_N\| \|q_N\|_Q}$$

$$0 < \tilde{\beta}_2(k) \leq \inf_{0 \neq q_N \in \mathbb{Q}_{k-2}} \sup_{0 \neq v_N \in \mathbb{V}_k} \frac{b(v_N, q_N)}{\|v_N\| \|q_N\|_Q}$$

$$0 < \tilde{\beta}_3(k) \leq \inf_{0 \neq q_N \in \mathbb{Q}_{k-1, \text{cont}}} \sup_{0 \neq v_N \in \mathbb{V}_k} \frac{b(v_N, q_N)}{\|v_N\| \|q_N\|_Q}$$

$$0 < \tilde{\beta}_4 \leq \inf_{0 \neq q_N \in \mathbb{Q}'_{k-1, \text{cont}}} \sup_{0 \neq v_N \in \mathbb{V}_k} \frac{b(v_N, q_N)}{\|v_N\| \|q_N\|_Q}$$

Proof. The result for $\mathbb{P}_{k-1}$ has been shown in \cite{47}. Furthermore, the inf-sup-constant $\tilde{\beta}_1$ of a single element of this type is independent both of $h$ and $k$, see \cite{6}. With the macroelement technique in \cite{44} one can then conclude that a whole mesh of elements of this type is inf-sup-stable independently of $h$ and $k$. The result for $\mathbb{Q}_{k-2}$ has been proved in \cite{47}. However, $\tilde{\beta}_2$ is not independent of the polynomial degree $k$. More precisely,

$$\tilde{\beta}_2 \geq k^{-\frac{d+1}{2}}$$

with $C$ independent of $k$ and $h$, see \cite{47}. The Taylor-Hood element is inf-sup-stable with respect to $h$ \cite{15}. However, the inf-sup-constant $\tilde{\beta}_3$ degrades with $k$ \cite{3}. The result for $\mathbb{Q}'_{k-1, \text{cont}}$ has been proved in \cite{2}. \qed

In a next step, the spaces are equipped with basis functions. The Legendre polynomials on $(-1, 1)$ are defined as

$$L_i(x) = \frac{1}{2^i i!} \frac{d^i}{dx^i} (x^2 - 1)^i.$$ 

They form an orthogonal system, e.g.

$$\int_{-1}^{1} L_i(x) L_j(x) \, dx = \delta_{ij} \frac{2}{2i - 1}.$$ 

The shape functions for the 2D and 3D reference element of the discontinuous pressure spaces $\mathbb{P}_{k-1}$ and $\mathbb{Q}_{k-2}$, can now be constructed by taking products, i.e.

$$L_{ij}(x, y) = L_i(x) L_j(y) \quad 0 \leq i, j,$$

$$L_{ijm}(x, y, z) = L_i(x) L_j(y) L_m(z) \quad 0 \leq i, j, m$$

where the indices $i$, $j$ and $m$ are running to some upper limit depending on the maximal polynomial degree $k$ and the choice of the elements for the pressure. Because of $p_N \in \mathbb{Q}_N \subset L^2$ continuity across element boundaries is not necessary, and therefore these polynomials are the most convenient choice. The basis $[\Phi_{\text{disc}, p}] = [\phi_{1}^p, \ldots, \phi_{m_p}^p]$ is introduced as the set of all piecewise discontinuous Legendre polynomial functions under the mapping $\Phi_n$. The support of each basis function consists of one element only. However, for the velocity variable $u_N$ and the pressure variable $p_N$ in the spaces $\mathbb{Q}_{k-1, \text{cont}}$ and $\mathbb{Q}'_{k-1, \text{cont}}$ the continuity across element boundaries is required. Therefore, the integrated Legendre polynomials

$$\tilde{L}_i(x) = \gamma_i \int_{-1}^{1} L_{i-1}(s) \, ds \quad i \geq 2 \quad \text{and} \quad \tilde{L}_{0/1}(x) = \begin{cases} 1 & x < 0 \\ \frac{1 + x}{2} & x \geq 0 \end{cases}$$

with $\gamma_i = \frac{2}{2i - 1}$.
with some scaling factor $\gamma_i$ are preferred. Note that
\[
\tilde{L}_i(x) = \beta_i (L_i(x) - L_{i-2}(x)) \quad \text{with } \beta_i > 0, i \geq 2.
\]

In the following we use $\gamma_i = 1$ and $\beta_i = \frac{1}{2^{i-1}}$. The shape functions for 2D and 3D can now be constructed again by taking products
\[
\tilde{L}_{ij}(x, y) = \tilde{L}_i(x) \tilde{L}_j(y) \quad 0 \leq i, j \leq k,
\]
\[
\tilde{L}_{ijm}(x, y, z) = \tilde{L}_i(x) \tilde{L}_j(y) \tilde{L}_m(z) \quad 0 \leq i, j, m \leq k,
\]
on the reference element, respectively. Since $\tilde{L}_i(\pm1) = 0$ for $i \geq 2$, the global basis functions for the continuous pressure spaces $Q_{k-1, \text{cont}}$ and $Q_{k-1, \text{disc}}$ are constructed in the usual way. The global functions $\phi_i^n$ can be divided into four groups,

1. the vertex functions,
2. the edge bubble functions,
3. face bubble functions (only for $d = 3$),
4. the interior bubble functions,

locally on each element $\mathcal{R}_e$, and globally on $\Omega$. We denote them again with $[\Phi_{\text{cont}, p}] = [\phi_1^p, \ldots, \phi_m^p]$. In the case of pure Dirichlet boundary conditions the space has to be modified since $Q_N \subset \mathbb{L}_0^2(\Omega)$. Since $\int_{-1}^1 \tilde{L}_i(x) \, dx = 0$ and $\int_{-1}^1 L_i(x) \, dx = 0$ for $i \geq 2$, this modification does not affect the high order basis functions. We refer the interested reader to [23].

The basis functions for the space $\mathbb{V}_N$ are functions with values in $\mathbb{R}^d$. They can be obtained from $[\Phi_{\text{cont}, p}]$ in the following way. Let $\mathcal{D} = \{i, i = 1, \ldots, m, \phi_i^n |_{\Gamma_0} = 0\}$ be the set of all indices corresponding to basis functions vanishing at the Dirichlet boundary condition and
\[
[\Phi_u, 1] = [\phi_i^n]_{i \in \mathcal{D}} := [\psi_i^n]. \quad (14)
\]

Then,
\[
[\Phi_u] = [\phi_1^n, \ldots, \phi_m^n] := \left[ \begin{array}{c} \psi_1^n \\ 0 \\ \vdots \\ 0 \\ \psi_m^n \end{array} \right], \quad (15)
\]
are the basis functions for the $\mathbb{V}_N$ for $d = 3$. The definition for $d = 2$ is similar.

Let
\[
A = (a_{ij})_{i,j=1}^n = \left[ a \left( \phi_i^n, \phi_j^n \right) \right]_{i,j=1}^n, \\
B = (b_{ij})_{i,j=1}^{n,m} = \left[ b \left( \phi_i^n, \phi_j^m \right) \right]_{i,j=1}^{n,m},
\]
\[
C = (c_{ij})_{i,j=1}^m = \left[ c \left( \phi_i^p, \phi_j^p \right) \right]_{i,j=1}^m. \quad (16)
\]

Then, the formulation (5), (6) is equivalent to the solution of a linear system of algebraic equations
\[
K \begin{bmatrix} u_N \\ p_N \end{bmatrix} = \begin{bmatrix} f_N \\ 0 \end{bmatrix} = \begin{bmatrix} A & B^T \\ B & -C \end{bmatrix} \begin{bmatrix} u_N \\ p_N \end{bmatrix} = \begin{bmatrix} f_N \\ 0 \end{bmatrix}, \quad (17)
\]
where $f_N = [f_j]_{j=1}^N = [F(\phi_j^n)]_{j=1}^n$. Using the FE isomorphism, the approximate solutions $u_N$ and $p_N$ are obtained as $u_N = [\Phi_u]u_N$ and $p_N = [\Phi_{\text{disc}, p}]p_N$ or $p_N = [\Phi_{\text{cont}, p}]p_N$, respectively. Note that the matrix $B$ has full rank and we have $C = 0$ for the Stokes problem.
4 The solution of the linear system

This subsection is devoted to the solution of (17). The matrix $A$ comes from the discretization of the velocity or displacement part and is symmetric positive definite. Since the matrix $B$ has full rank, the whole matrix $K$ is non-singular. Moreover, the Schur complement $S = C + BA^{-1}B^T$ is also symmetric positive definite.

Since the system matrix $K = \begin{bmatrix} A & B^T \\ B & -C \end{bmatrix}$ is indefinite, one cannot use the preconditioned conjugate gradient (PCG) method for the solution of the system. Due to the structure of $K$, we are able to use the preconditioned Bramble-Pasciak-CG, see [12].

In detail, let $\hat{A}$ and $\hat{S}$ be preconditioners for $A$ and the Schur complement $S$ with

$$\gamma_0 \hat{A} \leq A \leq \gamma_0 \hat{A}, \quad \gamma_1 \hat{S} \leq S \leq \gamma_1 \hat{S},$$

respectively, where $\gamma_0 > 1$. The matrix $K$ in (17) is formally preconditioned by the matrix

$$L^{-1} = \begin{bmatrix} \hat{A} & 0 \\ B & -\hat{S} \end{bmatrix}^{-1} = \begin{bmatrix} \hat{A}^{-1} & 0 \\ \hat{S}^{-1}B\hat{A}^{-1} & -\hat{S}^{-1} \end{bmatrix}.$$

In the non standard inner product $(\cdot, \cdot)_H = (H^{-1} \cdot, \cdot)$ with $H = \begin{bmatrix} A - \hat{A} & 0 \\ 0 & \hat{S} \end{bmatrix}$. In other words, the multiplication of (17) with $HL^{-1}$ from left yields to

$$T \begin{bmatrix} u_N \\ p_N \end{bmatrix} = \begin{bmatrix} (A - \hat{A})\hat{A}^{-1}f \\ B\hat{A}^{-1}f \end{bmatrix}$$

with the matrix

$$T := HL^{-1}K = \begin{bmatrix} (A - \hat{A})\hat{A}^{-1}A & (A - \hat{A})\hat{A}^{-1}B^T \\ B\hat{A}^{-1}(A - \hat{A}) & B\hat{A}^{-1}B^T \end{bmatrix}.$$

This matrix is symmetric positive definite with respect to the standard inner product. Therefore, the PCG-method can be used with the preconditioner

$$\hat{T} = \begin{bmatrix} A - \hat{A} & 0 \\ 0 & \hat{S} \end{bmatrix}.$$

We have the following theorem. [12], see also [49] for improved estimates.

**Theorem 4.1.** Let $T$ be defined by (19). Let us assume that $A$ is symmetric positive definite and $B$ has maximal rank. Moreover, let $\hat{A}$ and $\hat{S}$ be preconditioners for $A$ and the Schur complement $S$ satisfying (18). Let $\hat{T}$ be defined by (20). Then, the condition number estimates

$$\min\{1, \gamma_1\} \overline{\tau} \hat{T} \leq T \leq \max\{1, \overline{\tau}\} \overline{\tau} \hat{T}$$

hold where $\overline{\gamma} = \frac{1 - \sqrt{\alpha}}{1 - \alpha},$ and $\overline{\tau} = \frac{1 + \sqrt{\alpha}}{1 - \alpha}$ with $\alpha = 1 - \frac{1}{\gamma_0}$.

Summarizing, $\hat{T}$ is a good preconditioner for $T$ if and only if $\hat{A}$ and $\hat{S}$ are good preconditioners for $A$ and $S$ respectively, cf. (18). In the next two subsections, these preconditioners are defined. The final condition number estimates are stated in subsection 4.3.
4.1 The preconditioner for the elliptic part

This preconditioner corresponds to the bilinear form \( a(\cdot, \cdot) \) which is symmetric and bounded elliptic bilinear form on \( V \subset H^1(\Omega, \mathbb{R}^d) \).

We use DD-preconditioner with inexact subproblem solvers. Such a type of solver has been analyzed from the algebraic point of view by Nepomnyaschikh, \[34\]. More precisely, the overlapping domain decomposition splitting is taken from Pavarino \[37\]. The subproblem solver is the preconditioner of \[9\] which has been developed for scalar elliptic problems and a scalar \( hp \)-FEM basis. In order to introduce this preconditioner, let

\[
\mathcal{A} = \int_{\Omega} \nabla[\Phi_{u,1}] \cdot \nabla[\Phi_{u,1}] \, dx
\]

be the corresponding stiffness matrix for the Laplacian with respect to the scalar basis \( [\Phi_{u,1}] = [\psi_{u,i}^{(1)}] \) \[14\].

We give only a very brief definition of the preconditioner. For a given node \( v \), let

\[
\Omega_v = \left\{ \bigcup_s \mathcal{R}_s, v \subset \mathcal{R}_s \right\}
\]

be the closed patch associated to a node \( v \) of the finite element mesh, see Figure 1. Let \( J(v) = [j_1^v, \ldots, j_m^v] \) be the index set of all basis functions with \( \text{supp}(\psi_{u,j}) \subset \Omega_v \) and \( J(0) \) the index set of all \( m_v \) global vertex functions (V) which are ordered first. Let \( P_v \in \mathbb{R}^n_v \times N \) be the Boolean matrices with the entries

\[
[P_v]_{ij} = \begin{cases} 
1 & \text{if } j = j_i^v, 1 \leq i \leq n_v \\
0 & \text{else}
\end{cases}
\]

and \( [P_0]_{ij} = \begin{cases} 
1 & \text{if } i = j \leq m_v \\
0 & \text{else}
\end{cases} \).

Finally, let

\[
C_v = \left[ a(\psi_{u,i}^{(1)}, \psi_{u,k}^{(1)}) \right]_{i,k=1}^{n_v}
\]

be the index set of all basis functions with \( \text{supp}(\psi_{u,i}^{(1)}) \subset \Omega_v \) and \( J(0) \) the index set of all \( m_v \) global vertex functions (V) which are ordered first. Let \( P_v \in \mathbb{R}^n_v \times N \) be the Boolean matrices with the entries

\[
[P_v]_{ij} = \begin{cases} 
1 & \text{if } j = j_i^v, 1 \leq i \leq n_v \\
0 & \text{else}
\end{cases} \]

and \( [P_0]_{ij} = \begin{cases} 
1 & \text{if } i = j \leq m_v \\
0 & \text{else}
\end{cases} \).

Finally, let

\[
C_\tau = \left[ a(\psi_{u,i}^{(1)}, \psi_{u,k}^{(1)}) \right]_{i,k=1}^{n_v}
\]

be the index set of all basis functions with \( \text{supp}(\psi_{u,i}^{(1)}) \subset \Omega_v \) and \( J(0) \) the index set of all \( m_v \) global vertex functions (V) which are ordered first. Let \( P_v \in \mathbb{R}^n_v \times N \) be the Boolean matrices with the entries

\[
[P_v]_{ij} = \begin{cases} 
1 & \text{if } j = j_i^v, 1 \leq i \leq n_v \\
0 & \text{else}
\end{cases} \]

and \( [P_0]_{ij} = \begin{cases} 
1 & \text{if } i = j \leq m_v \\
0 & \text{else}
\end{cases} \).

Finally, let

\[
C_\tau = \left[ a(\psi_{u,i}^{(1)}, \psi_{u,k}^{(1)}) \right]_{i,k=1}^{n_v}
\]

be the index set of all basis functions with \( \text{supp}(\psi_{u,i}^{(1)}) \subset \Omega_v \) and \( J(0) \) the index set of all \( m_v \) global vertex functions (V) which are ordered first. Let \( P_v \in \mathbb{R}^n_v \times N \) be the Boolean matrices with the entries

\[
[P_v]_{ij} = \begin{cases} 
1 & \text{if } j = j_i^v, 1 \leq i \leq n_v \\
0 & \text{else}
\end{cases} \]

and \( [P_0]_{ij} = \begin{cases} 
1 & \text{if } i = j \leq m_v \\
0 & \text{else}
\end{cases} \).

In the same way, \( C_0 \) corresponding to the set \( J(0) \) are introduced. Finally, the ASM preconditioner with inexact subproblem solvers for \( A \) \[21\] is defined by choosing the BPX-preconditioner \( C_{BPX} \) and the matrix \( \hat{C}_{3,p} \) as preconditioner for \( C_0 \) and \( C_v \), respectively. The matrix \( \hat{C}_{3,p} \) is the wavelet based preconditioner developed in \[9\] for the patches, see also \[8\] for more details. Summarizing, one obtains the preconditioner

\[
\hat{A}_{in,1}^{-1} = P_v^T C_{BPX}^{-1} P_v + \sum_v P_v^T \hat{C}_{3,p}^{-1} P_v
\]

with \( A \sim \hat{A}_{in,1} \), see \[21\]. Since the velocity has values in \( \mathbb{R}^d \), the preconditioner \[23\] has to be adapted to

\[
\hat{A}_{in,d} = \text{blockdiag} \left[ \hat{A}_{in,1} \right]_{i=1}^{d}
\]

Then, the next theorem \[4,3\] has been shown under the following assumption.
Assumption 4.2. Each patch \(\Omega_v\) corresponding to an interior node for \(d = 3\) is the union of eight hexahedrons, two in each space direction. Patches to Neumann nodes on faces or interior nodes for \(d = 2\) of \(\Omega\) are assumed to be the union of four hexahedrons.

Theorem 4.3. Let \(a(\cdot, \cdot)\) be a symmetric, bounded and elliptic bilinear form on \(V\). Let \(A\) and \(\hat{A}_{in,d}\) be defined by (17) and (24), respectively. Moreover, let us assume that Assumption 4.2 is satisfied. Then, the condition number estimate \(\kappa(\hat{A}_{in,d}^{-1}A) \lesssim (\log k \log \chi \log k)^3\) holds for any \(\chi > 1\) where the constant is independent on \(h\) and \(k\). Moreover, the action \(\hat{A}_{in,d}^{-1}\) requires \(O(N)\) operations.

Proof. The result \(\kappa(\hat{A}_{in,d}^{-1}A) \lesssim (\log k \log \chi \log k)^3\) has been proved in [9]. The assertion for \(d > 1\) follows straightforward by using (24) and (15).

4.2 The preconditioner for the Schur-complement

We have already mentioned that the Schur complement \(S = C + BA^{-1}B^\top\) is also symmetric positive definite. In order to develop an spd-preconditioner for \(S\), let

\[
M = \left[ \int_\Omega \phi_i^p(x) \phi_j^p(x) \, dx \right]_{i,j=1}^m
\]

be the mass matrix with respect to the basis \([\Phi_p]\). Then, it can be proved that

\[
\hat{\beta}_1^2 M \leq S \leq M
\]

for the Stokes equation if \(C = 0\), where \(\hat{\beta}_1\) is the inf-sup-constant (7), see e.g. [23]. Since \(c(\cdot, \cdot)\) is bounded and positive semidefinite on \(Q \subset L_2(\Omega, \mathbb{R}^d)\), relations (16) and (25) imply

\[
\hat{\beta}_1^2 M \leq S \leq M.
\]

4.2.1 Discontinuous pressure space \(Q_N\)

We consider now the case, that the pressure is chosen to be discontinuously. Then, Legendre polynomials are used as our local basis functions, see (10), (12). Due to the orthogonality relation (11), we introduce the diagonal matrix

\[
D = \left[ \delta_{ij} \int_\Omega \phi_i^p(x) \phi_j^p(x) \, dx \right]_{i,j=1}^m
\]

as preconditioner for \(S\). Then, the following result can be proved.

Theorem 4.4. Let \(D\) be defined by (27) and let \(S\) be the Schur complement \(S = C + BA^{-1}B^\top\) where \(A, B, C\) are defined by (16). Then, the spectral equivalence relation

\[
\hat{\beta}_1^2 D \lesssim S \lesssim D
\]

holds, where \(\hat{\beta}_1\) is the inf-sup-constant (7).

Proof. The orthogonality of the Legendre polynomials imply \(M \sim D\). The assertion follows now from (26). \(\square\)
4.2.2 Continuous pressure space $Q_N$

We consider now the case, that the pressure is chosen to be continuously. Then, integrated Legendre polynomials are used as our local basis functions, see (13), (14). In this case, the mass matrix $M$ has nonzero offdiagonal entries. In the $h$-version of the FEM, the matrix $M$ is well conditioned. For the $p$-version of the FEM, the condition number grows as $O(k^d)$, [30]. Therefore, an efficient solver for $M$ is required.

In a first step, we introduce the Pavarino preconditioner for the mass matrix, i.e.

$$
\hat{C}_M^{-1} = P_0^T P_0 + \sum_v P_v^T M_v^{-1} P_v 
$$

(28)

with

$$
M_v = \left[ \int_{\Omega_v} \left( \phi_{j_1}^v, \phi_{j_2}^v \right) \right]_{i,k=1}^{n_v}.
$$

(29)

cf. the similar definition (22), (23) for the Laplacian. Then, we are able to prove the following result.

**Theorem 4.5.** Let $Q_{k-1, \text{cont}}$ be the pressure space and let assumption (12) be satisfied. Moreover, let $M$ be the mass matrix (25) and $\hat{C}_M$ be defined by (28). Then, we have $M \sim \hat{C}_M$.

**Proof.** The steps of the proof are similar to the $H^1$-case, see [37]. We give only a sketch of the proof. A detailed proof is given in a forthcoming paper. Using the Lemma of Lions, proven by Nepomnyaschikh [32], a stable decomposition of the ASM-space is required. The technical details require the construction of an interpolation operator $T_k: Q_{k+1} / Q_0 \to Q_k / Q_0$, which has to be stable in the norm induced by the bilinear form, cf. Lemma 2 of [37]. In our case, the bilinear form is $(\cdot, \cdot)_{L^2}$. Therefore, we have to show that

$$
\|T_k u\|_{L^2} \leq c \|u\|_{L^2}.
$$

Introducing a basis of $Q_{k-1}$, the constant $c$ can be chosen as the maximal eigenvalue of the eigenvalue problem

$$(B_k \otimes B_k) (M_{k,1D} \otimes M_{k,1D}) (B_k \otimes B_k) \alpha = \lambda (M_{k,1D} \otimes M_{k,1D}) \alpha$$

where $B_k$ is the restriction matrix

$$
B_k = \begin{bmatrix}
1 & 0 & \cdots & 0 \\
0 & \ddots & \vdots & \vdots \\
\vdots & \ddots & 1 & \vdots \\
0 & \cdots & 0 & 1
\end{bmatrix} \in \mathbb{R}^{k+2,k+2}
$$

and $M_{k,1D}$ is the one-dimensional mass matrix on the unit interval

$$
M_{k,1D} = \left[ \int_{-1}^{1} \hat{L}_i(x) \hat{L}_j(x) \, dx \right]_{i,j=0}^{k+1} \in \mathbb{R}^{k+2,k+2}.
$$

(30)

With the properties of the Kronecker product the maximal eigenvalue is bounded iff the maximal eigenvalue of

$$
B_k M_{k,1D} B_k \alpha = \lambda M_{k,1D} \alpha
$$

is bounded. Finally, a calculation shows that

$$
M_{k,1D}^{-1} B_k M_{k,1D} B_k = B_k + V_k
$$

where $V_k = [v_0, \ldots, v_{k+1}]$ consists of zeros except for the vector $v_k = (w_{ik})_{i=0}^{k+1}$, where we have
\[
w_{ik} = \begin{cases} 
1 - (-1)^{i+k} (2k+3)(2i-1) & i \geq 2 \\
2 & i = 0, 1 \quad k \text{ even} \\
-1 & i = 0, 1 \quad k \text{ odd} \\
(2k-3)(2k-1)(2k+3) & (2k-3)(2k-1) \\
(2k-3)(2k-1) & (2k-3)(2k-1) 
\end{cases}
\]

Therefore, by elementary computations follows that

\[
\lambda_{\text{max}} (B_k + V_k) = 1 + w_{kk} = \frac{2(2k+1)}{2k-1} \leq 7,
\]

which proves the result.

In second step, we have a close look to the structure of the matrix \(M_v\). The typical model problem for \(d = 2\) is: \(\Omega_v = \Omega_{\text{ref}} = (-2, 2)^2\) is the union of four square elements. Let

\[
\zeta_1(x) = \frac{1}{2} \begin{cases} 
2 + x & x \in [-2, 0] \\
2 - x & x \in [0, 2] \\
0 & \text{else}
\end{cases},
\]

\[
\zeta_{2i-2}(x+1) = \begin{cases} 
\hat{L}_i(x) & |x| \leq 1 \quad i = 2, \ldots, k, \\
0 & \text{else}
\end{cases},
\]

\[
\zeta_{2i-1}(x-1) = \begin{cases} 
\hat{L}_i(x) & |x| \leq 1 \quad i = 2, \ldots, k, \\
0 & \text{else}
\end{cases}
\]

be the basis functions for the one-dimensional patch of two neighbouring intervals, cf. Figure 2. Moreover, the one-dimensional mass matrix

\[
M_{k,1D}^{\text{patch}} = [m_{ij}]_{i=1}^{2k-1} \quad \text{with} \quad m_{ij} = \int_{-2}^{2} \zeta_i(x) \zeta_j(x) \, dx
\]

is introduced. The relations (3) and (11) imply that

\[
m_{ij} = 0 \quad \text{for} \quad |i - j| > 4,
\]

\[\text{(31)}\]
e.g. the matrix \(M_{k,1D}^{\text{patch}}\) is a banded matrix. Using (14) and a proper ordering of the basis functions, we have

\[
M_v = M_{TH} = M_{k,1D}^{\text{patch}} \otimes M_{k,1D}^{\text{patch}} = I \otimes M_{k,1D}^{\text{patch}} + M_{k,1D}^{\text{patch}} \otimes I
\]

(32)

for the Taylor-Hood pressure space \(Q_{k-1,\text{cont}}\). Then, we are able to formulate the following
Theorem 4.6. Let \( Q_{k-1,{\text{cont}}} \) be the pressure space and \( \mathcal{M}_{TH} \) be defined by (32). Then, the system \( \mathcal{M}_{TH} \mathbf{u} = \mathbf{f} \) can be solved by Cholesky decomposition in \( \mathcal{O}(k^2) \) operations.

Proof. Let \( R_{k,1D} \) be the Cholesky decomposition of \( \mathcal{M}_{k,1D}^{\text{patch}} \), i.e.

\[
\mathcal{M}_{k,1D}^{\text{patch}} = R_{k,1D} \mathcal{R}_{k,1D}.
\]

Then, we have

\[
\mathcal{M}_{TH} = (I \otimes R_{k,1D}^\top)(R_{k,1D} \otimes I)(I \otimes R_{k,1D}).
\]

(33)

Relations (31) and (32) imply the assertion. □

Therefore, the solver for the mass matrix for the Taylor-Hood element has been found. For the Ainsworth-Coggings element \( Q_{k-1,{\text{cont}}} \), the matrix \( \mathcal{M}_{AC} = \mathcal{M}_x \) is not in a Kronecker product structure, since several rows and columns are removed from bottom and right, respectively. With the aid of the restriction matrices \( P_{i,j} = \begin{bmatrix} I & 0 \end{bmatrix} \in \mathbb{R}^{i \times j}, i \geq j \), we are able to write the matrix \( \mathcal{M}_{AC} \) in the block form

\[
\mathcal{M}_{AC} = \left[ m_{ij} P_{l,h}^\top \mathcal{M}_{k,1D}^{\text{patch}} P_{l,h}^\top \right]_{i,j=1}^{2k-1},
\]

(34)

where \( h_1 = l = 2k - 1, h_{2i} = h_{2i+1} = 2k - 1 - 2i, i = 1, \ldots, k - 1 \). The block Cholesky decomposition of the matrix

\[
I \otimes R_{k,1D}^\top = \left[ \delta_{ij} R_{k,1D}^\top \right]_{i,j=1}^{2k-1}
\]

in (33) can be generalized to

\[
\left[ \delta_{ij} P_{l,h}^\top R_{k,1D} P_{l,h} \right]_{i,j=1}^{2k-1}
\]

for the matrix in (34). This leads to a fast direct solver for what the following result is required.

Lemma 4.7. Let \( U = \left[ u_{ij} \right]_{i,j=1}^l \) be a symmetric positive definite matrix with its Cholesky decomposition \( U = R_{l,h} \), \( (h_i)_{i=1}^l \) be a monotonic non-increasing sequence of positive integers with \( h_1 = l \) and \( P_{i,j} = \begin{bmatrix} I & 0 \end{bmatrix} \in \mathbb{R}^{i \times j}, i \geq j \). Moreover, let

\[
U_{AC} = \left[ u_{ij} P_{l,h}^\top U P_{l,h} \right]_{i,j=1}^l
\]

be a block matrix with its block Cholesky decomposition

\[
R_{AC}^\top = \left[ \delta_{ij} P_{l,h}^\top R_{l,h} P_{l,h}^\top \right]_{i,j=1}^l
\]

Then, we have

\[
R_{AC}^\top U_{AC} R_{AC} = \left[ U_{AC,ij} \right]_{i,j=1}^l
\]

with \( U_{AC,ij} = u_{ij} P_{h_i,h_j} \) for \( i \leq j \) and \( U_{AC,ij} = u_{ij} P_{h_i,h_j}^\top \) else.

Proof. We compute now \( R_{AC}^\top U_{AC} R_{AC} \) and obtain

\[
R_{AC}^\top U_{AC} R_{AC} = \left[ u_{ij} P_{l,h_i}^\top R_{l,h_i} P_{l,h_i}^\top U P_{l,h_j} P_{l,h_j}^\top R_{l,h_j} P_{l,h_j} R_{l,h_j}^{-1} P_{l,h_j} \right]_{i,j=1}^l
\]

(35)
Since $R^{-T}$ is a lower triangular matrix, we have
\[
P_{l,h}^TR^{-T}P_{l,h}P_{l,h}^T = \begin{bmatrix} I & 0 \\ R_{11} & X & Y & 0 \\ 0 \\ R_{11} & 0 \end{bmatrix} = P_{l,h}^TR^{-T}
\]
Therefore, \( \mathcal{M}_A \) simplifies to
\[
R_{AC}^T U_{AC} R_{AC} = [u_{ij}P_{l,h}^TR^{-T}UR^{-1}P_{l,h}]_{i,j=1}^k = [u_{ij}P_{l,h}^TR^{-1}P_{l,h}]_{i,j=1}^k
\]
Together with $h_i \geq h_j$ for $i \leq j$, this proves the assertion.

Then, we are able to prove the following

**Theorem 4.8.** Let $Q_{k-1,\text{cont}}$ be the pressure space and $\mathcal{M}_A$ be defined by (34). Then, the system $\mathcal{M}_A u = f$ can be solved by Cholesky decomposition in $O(k^3)$ operations.

**Proof.** We apply Lemma 4.7 with the specifications $U = \mathcal{M}_A^{\text{patch}}$, $h_1 = l = 2k - 1$, $h_2 = h_{2i+1} = 2k - 1 - 2i$, $i = 1, \ldots, k-1$. Since $\mathcal{M}_A^{\text{patch}}$ has limited bandwidth, the matrix $R_{AC}$ has it, too. Therefore, $R_{AC}$ can be computed in $O(k^3)$ operations. With similar arguments, it can be proved that the system with the matrix $R_{AC}\mathcal{M}_A R_{AC}$ can be solved in $O(k^2)$ operations.

**Remark 4.9.**
1. If assumption 4.2 is satisfied, we have $\mathcal{M}_{T_H} \sim \mathcal{M}_v$. Then, also the system $\mathcal{M}_v u = f$ can be solved in $O(k^3)$ operations.
2. With the same arguments, it can be proved that $\mathcal{M}_v u = f$ can be solved in $O(k^3)$ for $d = 3$.
3. Summarizing, the system $\mathcal{M}_u = f$ with the global mass matrix $\mathcal{M}_D$ can be solved in optimal arithmetical complexity.

### 4.3 Final condition number estimates

We are now in the position to formulate our final result of this paper. Therefore, we introduce the matrix
\[
\hat{T} = \begin{bmatrix} A - \rho \hat{A}_{in,d} & 0 \\ 0 & D \end{bmatrix}
\]
where $c$ is some constant, see also (24), (27) for the definitions of $\hat{A}_{in,d}$ and $D$, respectively.

**Theorem 4.10.** Let $T$ and $\hat{T}$ be defined by (19) and (36), respectively. Let $K$ be the discretization matrix (17) of the mixed problem (2) by using the space pair $V_h$ and $P_{k-1}$ (9). Then, there exists a $\rho > 0$ such that
\[
\hat{T} \preceq T \preceq (\log k \log^3 \log k)^3 \hat{T}
\]
for any $\chi > 1$. Moreover, the solution of a system with the matrix $K$ (17) can be performed by using the preconditioned Bramble Pasciak-CG with the preconditioner $\hat{T}$ (36) in $O(N(\log N \log^3 \log N)^{3/2})$ operations.

**Proof.** In order to prove the first assertion, we apply theorem 4.7 and verify the assumptions (18). Theorem 4.3 implies that there exists a constant $\rho > 0$ such that $\gamma_0 \sim 1$ whereas $(\log k \log^3 \log k)^3 \preceq \gamma_0$. Due to lemma 3.1, the inf-sup constant $\delta_1$ is independent of $h$ and $k$. Finally, theorem 4.4 implies $S \sim D$. Therefore, $\gamma_1 \sim 1$ and $\tau_1 \sim 1$. This proves the first assertion. Since a multiplication with each of the involved matrices can be performed in $O(N)$ operations, see theorem 4.3, the second result follows from the properties of the PCG-method.
Remark 4.11. 1. In order to apply the Bramble-Pasciak CG, the parameter $\rho$ in (36) has to be chosen properly. If $\rho$ is too large the matrix $\hat{T}$ in (36) becomes indefinite. If $\rho$ is chosen too small the upper constant $\gamma_0$ becomes larger which results in worse condition number estimates in theorem 4.10. Rough estimates of $\rho$ can be obtained by a eigenvalue computations in a precomputing step.

2. An alternative to the Bramble-Pasciak-CG is the MINRES algorithm. Then, using the ingredients of lemma 3.1, theorem 4.3 and theorem 4.4, a solution in quasioptimal complexity can also be shown, see [23] for the theoretical background.

3. We have derived a quasioptimal solver for the Stokes problem, since the bilinear form $a(\cdot, \cdot)$ in (3) is $H^1$ elliptic. For the linear elasticity problem, the bilinear form $a(\cdot, \cdot)$ in (4) is $H^1$ elliptic. The constants in the second inequality (2) do not depend on the choice the parameters $E$ and $\nu$. However, the constants depend on the geometry of the domain. Since also $c(\cdot, \cdot)$ in (4) does not depend on $E$ or $\nu$, which is the case for nearly incompressible material, we have developed a robust $hp$-FEM solver for linear elasticity in quasioptimal complexity.

4. The results of the theorem remain true if the matrix $\hat{A}_{in,d}$ in (36) or equivalently $\hat{A}_{in,1}$ in (24) is replaced by another quasioptimal solver for the Laplace equation.

5 Numerical experiments

Finally, some numerical experiments are presented.

Computation of the inf-sup constant

Since the condition number estimates in theorem 4.10 depend strongly on the inf-sup constant $\tilde{\beta}_1$ (7), figure 3 shows the behavior of the inf-sup constant on the polynomial degree for different types of single elements. We observe that the value of the inverse of the inf-sup-constant of the $Q_k - Q_{k-2}$, disc-element tends to converge to a fixed value. The inverse of the inf-sup-constant of the $Q_k - P_{k-1}$, disc-element increases as $k$ increases.

![Figure 3: Dependence of the discrete inf-sup constant of several single elements on the polynomial degree $k$, for $d = 2$ (left) and $d = 3$ (right).](image-url)
$k$ increases, which coincides with the theory. Nevertheless also in the later case these values are still of moderate size in 2D. However, in 3D these values reach unacceptable values.

**Iteration numbers of the preconditioned Bramble Pasciak CG**

In all experiments of this paragraph, the system (17) for the Stokes problem is solved by the Bramble-Pasciak-CG with the preconditioner (36). A relative accuracy of $\epsilon = 10^{-5}$ is chosen. The domain $\Omega = [-1,1]^d$, $d = 2, 3$, respectively, is used with pure Dirichlet boundary conditions, e.g. $\partial \Omega = \Gamma_0$. The mesh consists of the union of $2^d$, $d = 2, 3$ congruent elements. The iteration numbers of the preconditioned Bramble-Pasciak-CG are displayed in figure 4 for the $Q_k-P_{k-1,\text{disc}}$-element and the $Q_k-Q_{k-2,\text{disc}}$-element with discontinuous pressure.

![Figure 4: Iteration numbers of the preconditioned Bramble-Pasciak-CG for different elements, $d = 2$ (left), $d = 3$ (right).](image)

The iteration numbers for the $Q_k-P_{k-1,\text{disc}}$-element are lower than for the $Q_k-Q_{k-2,\text{disc}}$-element. Note that the inf-sup-constant is independent of the polynomial degrees $k$ for the $Q_k-P_{k-1,\text{disc}}$, see lemma 3.1. Due to the wavelet preconditioner for the matrix $A$, which is optimal only up to some logarithmic term, see theorem 4.3, the iteration numbers grow moderately in this case. The inf-sup-constant for the $Q_k-Q_{k-2,\text{disc}}$-element depends on the polynomial degree $k$. This results in higher iteration numbers for the $Q_k-Q_{k-2,\text{disc}}$-element. Although the proposed solver is not optimal in complexity for the $Q_k-Q_{k-2,\text{disc}}$-element, the iteration numbers of the Bramble-Pasciak-CG differ only slightly in comparison to the iteration numbers of the Bramble-Pasciak-CG for the $Q_k-P_{k-1,\text{disc}}$-element if $k \leq 100$. This situation becomes different in 3D where the iteration numbers for the $Q_k-Q_{k-2,\text{disc}}$-element are much higher than for the $Q_k-P_{k-1,\text{disc}}$-element already for $k \geq 10$.

The next figure presents the iteration numbers for the Taylor-Hood-element and the Ainsworth-Coggins-Element in 2D. Again the iteration numbers for the Ainsworth-Coggins-element, where the inf-sup-constant is independent of the polynomial degree are lower than for the Taylor-Hood-element. As for the $Q_k-P_{k-1,\text{disc}}$, the numbers of iterations depend only on the quasi-optimality of the wavelet preconditioner. The dependence of the inf-sup-constant results in an increase of the iteration numbers for the Taylor-Hood-element.
Preconditioner for the mass matrix

The last experiments show the quality of the preconditioner $\hat{C}_M^{-1}$ for the mass matrix $M$. Theorem 4.5 gives theoretical eigenvalue bounds of $\hat{C}_M^{-1}M$ for the tensor product space $Q_{k-1,\text{cont}}$. The eigenvalue bounds $\lambda_{\text{min}}$ and $\lambda_{\text{max}}$ are computed for the space $Q'_{k-1,\text{cont}}$, see [9], which corresponds to the Ainsworth-Coggins element. Table 1 displays $\lambda_{\text{min}}$ for the case of Cartesian grid of $m \times m$ squares and polynomial degree $k$. (space $Q'_{k-1,\text{cont}}$). A refinement of the Cartesian grid with respect to $k$ and the number of

elements $m$ does not affect in an increase of the condition number of $\hat{C}_M^{-1}M$ for the Ainsworth-Coggins element. In all experiments, we have also $\lambda_{\text{max}} \leq 5$.

Acknowledgement: The authors want to thank Veronika Pillwein from RISC, University of Linz, Austria for helpful hints for the proof of Theorem 4.5. With this report the authors want to appreciate the lectures on “Domain decomposition methods” given by Sergey Nepomnyaschikh during his stays in Chemnitz in 1999 and in Linz in 2009. [33].
